Example 66. (as at the end of last class) Determine the QR decomposition of $A = \begin{bmatrix} 0 & 2 & 1 \\ 3 & 1 & 1 \\ 0 & 0 & 1 \\ 0 & 0 & 1 \end{bmatrix}$.

Solution. (using Sage)

```
Sage] A = matrix([[0,2,1],[3,1,1],[0,0,1],[0,0,1]])
Sage] A = matrix(QQbar, [[0,2,1],[3,1,1],[0,0,1],[0,0,1]])
Sage] A.QR(full=false)
```

$$\left(\begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0.7071067811865475? \\ 0 & 0 & 0.7071067811865475? \end{bmatrix}, \begin{bmatrix} 3 & 1 & 1 \\ 0 & 2 & 1 \\ 0 & 0 & 1.414213562373095? \end{bmatrix} \right)$$

Comment. Can you figure out what happens if you omit the `full=false`? Check out the comment under **Variations** for the QR decomposition in the previous lecture sketch. On the other hand, the `QQbar` is telling Sage to compute with algebraic numbers (instead of just rational numbers); if omitted, it would complain that square roots are not available.

Example 67. Determine the QR decomposition of $A = \begin{bmatrix} 1 & 2 & 4 \\ 0 & 0 & -5 \\ 0 & 3 & 6 \end{bmatrix}$.

Solution. We first apply Gram–Schmidt orthonormalization to the columns of A.

- $\boldsymbol{b}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$, so that $\boldsymbol{q}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$.
- $\boldsymbol{b}_2 = \begin{bmatrix} 2 \\ 0 \\ 3 \end{bmatrix} - \left(\begin{bmatrix} 2 \\ 0 \\ 3 \end{bmatrix} \cdot \boldsymbol{q}_1 \right) \boldsymbol{q}_1 = \begin{bmatrix} 0 \\ 0 \\ 3 \end{bmatrix}$, so that $\boldsymbol{q}_2 = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$.
- $\boldsymbol{b}_3 = \begin{bmatrix} 4 \\ -5 \\ 6 \end{bmatrix} - \left(\begin{bmatrix} 4 \\ -5 \\ 6 \end{bmatrix} \cdot \boldsymbol{q}_1 \right) \boldsymbol{q}_1 - \left(\begin{bmatrix} 4 \\ -5 \\ 6 \end{bmatrix} \cdot \boldsymbol{q}_2 \right) \boldsymbol{q}_2 = \begin{bmatrix} 0 \\ -5 \\ 0 \end{bmatrix}$, so that $\boldsymbol{q}_3 = \begin{bmatrix} 0 \\ -1 \\ 0 \end{bmatrix}$.

Therefore, $Q = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix}$. Finally, $R = Q^T A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{bmatrix} \begin{bmatrix} 1 & 2 & 4 \\ 0 & 0 & -5 \\ 0 & 3 & 6 \end{bmatrix} = \begin{bmatrix} 1 & 2 & 4 \\ 0 & 3 & 6 \\ 0 & 0 & 5 \end{bmatrix}$.

In conclusion, we have found the QR decomposition: $\underbrace{\begin{bmatrix} 1 & 2 & 4 \\ 0 & 0 & -5 \\ 0 & 3 & 6 \end{bmatrix}}_{A} = \underbrace{\begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{bmatrix}}_{Q} \underbrace{\begin{bmatrix} 1 & 2 & 4 \\ 0 & 3 & 6 \\ 0 & 0 & 5 \end{bmatrix}}_{R}$

Comment. As noted before, we actually could write down R without any additional computation. Indeed, realize that the second column of R, that is $[2, 3, 0]^T$ means that

$$\text{2nd col of } A = 2\boldsymbol{q}_1 + 3\boldsymbol{q}_2.$$

Which we already knew from our computation of $\boldsymbol{q}_2$! Also, by construction, we know that the second column of A is a linear combination of $\boldsymbol{q}_1$ and $\boldsymbol{q}_2$ only, and that $\boldsymbol{q}_3$ enters the story later on. This corresponds to the fact that R is always upper triangular.

Letting Sage do the work for us.

```
Sage] A = matrix(QQbar, [[1,2,4], [0,0,-5], [0,3,6]])
Sage] A.QR()
```

$$\left(\begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 2 & 4 \\ 0 & 3 & 6 \\ 0 & 0 & 5 \end{bmatrix} \right)$$

Example 68. (review) A matrix A has orthonormal columns $\iff$ $A^T A = I$.

Definition 69. An **orthogonal matrix** is a square matrix with orthonormal columns.

[This is not a typo (but a confusing convention): the columns need to be orthonormal, not just orthogonal.]

An $n \times n$ matrix Q is orthogonal $\iff$ $Q^T Q = I$

In other words, $Q^{-1} = Q^T$.
